## 1. INTRODUCTION

R&D and innovation activities are complex experimental processes with uncertain outcomes. There is uncertainty concerning whether new products, processes and services are introduced, whether they become a (commercial) success, and to what extent they lead to economic growth. Given this highly experimental nature, policy makers are interested in identifying effective ways to deal with this uncertainty, so they are better able to assess where innovation and R&D is more likely to occur. This information will ultimately result in a more effective policy to support R&D and innovation activities. The goal of this work package is to provide such insights by answering the question in how to identify sectors with the largest need and potential for private sector R&D investment.

Innovation is the result of a recombination of existing knowledge, skills and competences, in Joseph A. Schumpeter's classic formulation.<sup>1</sup> Be that as it may, it is not expected that any recombination will lead to innovation. Specifically the nature of the knowledge, skills and competences will be a determining factor. Knowledge, skills and competences that are similar will be easy to combine; however, one might question the level of newness that comes out of such a process. Conversely, knowledge, skills and competences that are radically different and unlike will be nearly impossible to combine as there are no complementarities. Attempting to learn from knowledge, skills and competences that are radically different from your own is potentially problematic as one often lacks the necessary absorptive capacity.<sup>2</sup> Although not impossible, the probability of an innovation to emerge from such a recombination process will be smaller.<sup>3</sup> Thus, innovation is expected to emerge in a situation where firms, as loci of innovation, in any given sector have access to knowledge that is different to their own, but not so different that they are not able to process this external knowledge. The potential for private sector R&D investments would thus depend on how the knowledge skills and competences of firms in a particular sector relates to the knowledge, skills, and competences of firm in other sectors in the region. The regional context is important as innovation activities are often regionally bounded<sup>4</sup> and dependent on innovation activities of other firms in the region.<sup>5</sup>

The extent to which firms and sectors in a given region have related knowledge, skills and competences is a strong predictor of the innovative capabilities of firms, sector and regions. Consequently, the concepts of related variety and skill or industry relatedness, which emerged following the study by Frenken, Van Oort and Verburg,<sup>6</sup> are the foundation of this work package as a theoretical foundation and empirical method to identify sectors that have the greatest need and potential for private R&D investments.

---

<sup>1</sup> Schumpeter (1934).

<sup>2</sup> Cohen & Levinthal (1990).

<sup>3</sup> If innovation occurs, it will be more likely to be qualified as break-through innovation (Castaldi et al 2013).

<sup>4</sup> Audretsch & Feldman (1996).

<sup>5</sup> Fritsch & Franke (2004).

<sup>6</sup> Frenken, Van Oort, & Verburg (2007).

The concepts of related variety and skill relatedness build heavily on the work on (cognitive) proximity by Nooteboom<sup>7</sup> and Boschma<sup>8</sup>. This provides a more nuanced picture on how effective knowledge spillovers between sectors and firms take place. It is expected that high levels of relatedness and related variety “*improve the opportunities to interact, copy, modify and recombine ideas, practices and technologies*” (Frenken et al 2007: p. 687). Consequently, the more industries and firms rely on related knowledge, skills, and competences in the region, the more learning opportunities will arise. This will again positively affect the levels of innovation and regional economic performance.

Despite the relative short history, the concepts of relatedness and related variety have emerged as a robust concept to predict regional economic development, including innovation activities and performance. It is therefore not surprising that the relatedness and related variety feature as core concepts with the regional smart specialization discussion in current EU innovation policy debate.<sup>9</sup> This increasing body of evidence would argue that policy-makers are encouraged to become familiar with these concepts and their underlying mechanisms. We argue that these concepts are particularly valuable in light of the earlier-mentioned experimental and subsequent uncertain nature of innovation. This nature makes it challenging for policy-makers to ex-ante identify areas that are especially receptive for innovation support and where policy has the largest impact. Relatedness and related variety have a strong predictive power on innovation activities, R&D uptake, and subsequent innovative performance. Thus related variety and relatedness can be used to assess sectors that are more likely to engage in successful innovation activities.

Local, regional, and national policy-makers can based on their detailed knowledge of national, regional and local structures identify industries, technologies and competences that are related and for that reason are prone to successfully engage in innovative activities. For example, identifying sectors that currently are not demonstrate to be highly innovative or R&D intensive but are closely related to sectors that are. The purpose of this document is to provide policy-makers insights on the importance of relatedness and related variety for regional economic performance and innovation, how relatedness and related variety can be measured, and how they can identify relatedness and related variety in their local, regional and national structures.

## 2. THE ROBUST EFFECTS OF RELATED VARIETY AND RELATEDNESS

The interest in the concept of related variety and relatedness as an approach to explain economic activities has gained momentum since the paper by Frenken, Van Oort and Verburg<sup>10</sup> that investigated the impact of related and unrelated variety on regional economic growth in the Netherlands. The concepts as such provide an explanation on the effectiveness of knowledge spillovers combining features of the two dominant, contradicting features of agglomeration economies. These features explain how different knowledge spill-overs contribute to the overall economic

<sup>7</sup> Nooteboom (2000).

<sup>8</sup> Boschma, R. (2005).

<sup>9</sup> McCann & Ortega-Argiles (2013); Boschma & Gianelle (2013).

<sup>10</sup> Frenken, Van Oort, & Verburg (2007).

performance of regions and cities. On the one hand we have agglomeration externalities that emphasize the importance of regional specialization, often referred to as Marshall-Arrow-Romer or MAR externalities.<sup>11</sup> Such regional specialization results in thick and specialized labor markets, the access to specialized suppliers and large markets, and promote regional knowledge spill-overs as firms rely on similar knowledge, skills and competences. This reliance on similar knowledge, skills and competences lead to high level of imitation and inter-firm labor mobility, which cause ideas to quickly spread through the system. These ideas have been highly influential in the development of cluster policies, which have been popular among policy-makers since the early 1990s. Cluster policies encourage regional specialization through supporting the further development of regions that are already strong in the region. The Norwegian Innovation Clusters programmes – Arena, NCE and GCE – are current examples of these types of policies.

As its apparent opposite there are agglomeration externalities as the result of diversified regional structures. These mechanisms are often referred to as Jacobs externalities, after the legendary urbanist Jane Jacobs.<sup>12</sup> In her thesis, it is not specialization but rather diversity in regional structures that are the trigger of new ideas, which would lead to new economic activities and subsequent regional economic growth. Empirical research has demonstrated positive and negative effects of both types of these externalities on regional economic performance. The ideas of Jane Jacobs have recently been taken up in the work of Richard Florida, who has had a strong influence on regional policy in the US and several European countries, including Norway, in recent years. Florida's work emphasizes promoting a regional culture that is open to a diversity of creative workers as a key mechanism for regional development.<sup>13</sup>

The concepts of related variety and relatedness are positioned somewhere in between these two approaches. This approach argues that knowledge spillovers are not expected between all sectors, as some level of complementary in knowledge is expected before effective knowledge transfers can take place.<sup>14</sup> Furthermore, too much proximity might hamper interactive learning and innovation as well.<sup>15</sup> Consequently, neither regional diversity nor regional specializations are beneficial per se. Instead, interactive learning, innovation and regional development occur when knowledge spills between (local) sectors when these sectors are technologically related. The concept of related variety argues that related variety leads to more knowledge spillovers, which will enhance regional growth and employment. Unrelated variety, which means that there are no apparent or only limited complementarities between sectors, has a portfolio effect that protects regions against shocks and negative influences like unemployment growth. Such portfolio effects might also be achieved in a setting of related variety if these sectors are subject to similar business cycle effects.<sup>16</sup> Policies based on related variety have been popular in the EU in recent years,

<sup>15</sup> Nooteboom (2000); Boschma (2005).

<sup>16</sup> Boschma (2015).

particularly through the Smart Specialization framework. However, with some exceptions, these approaches have not been widely used in Norway so far.

These concepts lend themselves well for empirical testing. It is therefore not surprising that over the last couple of years many studies of the effects of related variety have emerged. These studies have focused on various regions in Europe and the United States and covered nearly all industries. Sometimes making a sector specific distinction between high-tech and low-tech industries or more detailed sector specification.<sup>17</sup> The majority of these investigate broader regional economic effects of related variety and relatedness; for example the effect on:

- regional economic performance indicators like employment and unemployment rates, gross domestic product, productivity and value added growth;
- regional industrial branching, which refers to the emerge of new industries; and
- resilience, which is the ability of regions to recover from economic shocks.<sup>18</sup>

Those studies that investigate the effect of related and unrelated variety on regional economic performance indicators follow to a large extent the earlier-mentioned study on the Netherlands of Frenken, Van Oort and Verburg. In this study, the conclusion is rather clear that related variety positively affected employment growth while unrelated variety seems to dampen the negative effects of unemployment following an economic shock.<sup>19,20</sup> Furthermore, these studies also demonstrate considerable heterogeneity between industries.<sup>21</sup> These positive effects of related variety and relatedness are also visible when looking at labor productivity growth and value added, both on the regional level<sup>22</sup> but also on the level of individual plants.<sup>23</sup>

A second set of empirical studies are interested to understand how related variety and relatedness contribute to the entry of new industries into a given region, a phenomenon known as regional branching.<sup>24</sup> The argument behind this regional branching principle is that the existing industry structure in a given region can be a predictor on the emergence of prior non-existing industry activities. This has empirically been shown in the case of regions in Sweden<sup>25</sup> and Spain<sup>26</sup> and for metropolitan areas in the United States.<sup>27</sup> In addition to these quantitative oriented studies there are also a range of case studies that find similar effects of related variety on the emergence of sectors.<sup>28</sup> The importance of relatedness and related variety on regional economic performance and regional

<sup>27</sup> Essletzbichler (2015)

<sup>28</sup> Example of studies are: Steen & Hansen 2014; Shang 2013; Bugge & Oiestad 2015; Elola et al 2013; Parrilli & Zabala-Iturriagoitia 2014; Wink et al 2015; Tomlinson and & Branston 2014)

branching have also resulted that these terms are key within the regional Smart Specialization concept as an approach on how regions should target regional industrial development.<sup>29</sup>

More recently, the related variety has also been linked to resilience of regions. Resilience is defined as “*the ability of the region’s industrial, technological, labor force and institutional structure to adapt to the changing competitive, technological and market pressures, and opportunities that confronts its firm and workforce.*”<sup>30</sup> Related variety and relatedness contributes to the resilience of regions as related activities do not necessarily have to be subject to similar business cycles. Consequently, related variety could be assist regions in deal with economic shocks as individuals who lose jobs in one industry can more easily transfer to related (compared to unrelated) industries. This thesis was tested, and confirmed, for the Netherlands<sup>31</sup>, and also has shown to be the case of shipyards in Denmark and Sweden.<sup>32</sup>

### 3. MEASURING SKILL RELATEDNESS AND RELATED VARIETY

The previous sections have offered important insights on how relatedness and related variety in regional industrial structures affect regional economic performance in general, and innovation activities and performance in particular. The follow-up question would be that given the importance of relatedness and related variety on how it is possible to assess which firms and sectors can be regarded as related.

When identify relatedness among Norwegian industries, researchers often rely on relatedness based on the structure of the traditional industry classes, e.g. NACE. In this setup, industries are related when the first two-digits are similar while the third (and fourth) digit are different; all with the same four-digit industry class are considered similar while those with different two-digit industries are considered to be unrelated. While this measure might make sense on the surface there are some shortcomings: (i) there are clearly identified industries that according to this method will be considered unrelated but in reality are, e.g. IT services and IT manufacturing; and (ii) value chain relationships in more difficult to identify industries, e.g. oil and gas, are difficult to identify in such a setup.

In this study, we will instead rely on a measure of skill-relatedness based on labor mobility flows as introduced by Neffke & Henning (2013). We use this method because we assume that employees will move to those industries where their skills are valued; moving to industry where this is not the case employees potentially cannibalize on their own human capital, which might lead to lower (or negative) wage gains. Consequently, when we observe a high mobility between specific industries, their skills are higher valued, less human capital is destroyed, and thus skill-relatedness is high.<sup>33</sup>

---

<sup>29</sup> McCann & Ortega-Argiles (2013); Boschma & Gianelle (2013).

<sup>30</sup> Simmie & Martin (2010).

<sup>31</sup> Diodato & Weterings (2015).

<sup>32</sup> Holm et al (2015); Eriksson et al (2014).

<sup>33</sup> In some instances, in particular in moves between industries that are dominated by low-skills, these flows might represent low entry barriers or focus on general skills, rather than industry specific skill-sets.

This skill-relatedness is measured using the method by Neffke *et al.* (2012), which is strongly correlated to the method in Neffke & Henning (2013), but considerably easier to apply. Skill-relatedness  $SR_{ij}$  is calculated as follows:

$$SR_{ij} = \frac{F_{ij}/F}{(F_i/F)(F_j/F)} = F_{ij} \frac{F}{F_i F_j}$$

Where  $F_{ij}$  are the total number of employees moving from industry  $i$  to industry  $j$ ;  $F$  is the total number of employees that move in any given year;  $F_i$  are the number of individuals that leave a firm in industry  $i$ ; and  $F_j$  are the number of employees that enter a firm in industry  $j$ .

The distribution based on this skill-relatedness is highly skewed and following Neffke *et al.* (2012) we propose a transformation that maps the skill-relatedness on an interval between -1 and 1:

$$\widehat{SR}_{ij}^t = \frac{SR_{ij} - 1}{SR_{ij} + 1}$$

Skill-relatedness is based on all employees between the age of 18 and 65 whose primary income is obtained from a job where they work at least 20 hours a week on average, who moved to a new firm in the period 2000-2011. We identify this move by identifying all individuals that worked for a given firm in a specific industry one year but have changed employer, potentially also changed industry, in the year that follows. Due to the revision of the NACE system in 2007, we perform the analysis in two separate steps: First, we analyze all movements between industries for the period 2000-2007, and second, we do the same for the period 2008-2011.

In total, 537 different industries are identified based on 4-digit NACE codes in the period 2000-2007 and 459 industries in the period 2008-2011, which will give us a total of 287,832 unique industry pairs in the former period and 210,681 unique industry pairs in the latter period. There might be yearly variation on whether an industry pair is related; in particular small industries with relative few movements. To control for this noise, we take the yearly average of  $\widehat{SR}_{ij}^t$  over the period 2000-07, and again for 2008-11. In order to be considered related, industry pairs must meet the following two criteria:  $\widehat{SR}_{ij}^t > 0.25$  on average for the whole period, and  $\widehat{SR}_{ij}^t > 0$  in at least three of the seven years (2000-07) or two of the four years (2008-11). Based on this measure, a total of 6494 industry pairs are classified as related in the period 2000-07, and 6614 industry pairs are classed as related for the period 2008-11.

Appendix A provides the full list of related industries for the period 2000-07, while Appendix B does the same for the period 2008-11.

#### 4. CONCLUDING REMARKS

Relatedness and related variety in industry structures, measured quantitatively on large datasets but also using more detailed case studies, are used as an empirically robust approach to understand

patterns of regional economic growth, but recently also to understand changes in regional industrial composition, regional industrial resilience and the occurrence of innovation activities and subsequent innovation success. Given the broad application of these concepts to explain regional economic performance, relatedness and related variety play a central role in the EU's efforts to develop regional smart specialization strategies, which take its point of departure in a region's existing knowledge base, knowledge, skills, and competences when setting up a regional development agenda.

The robust empirical evidence on how relatedness and related variety affects regional economic performance and innovation would require policy-makers to become familiar with these concepts and their underlying mechanisms. This document aims to provide policy-makers insights on the importance of relatedness and related variety for regional economic performance and innovation; how this relatedness and related variety can be measured; and how relatedness and related variety can be identified in any given local, regional and national structure.
